#### Cheatsheet CS210

XOR TRUTH TABLE

## Logic Gates

AND =D- A·B NAND =D- A-B

OR ⇒ A+8

NOT -D- A XOR ⇒D→ A⊕B

#### Definitions

specific bit Recognizes Decoders patteins

chooses among various Multiplexors inputs

# Example of a decoder $D_1 = \vec{A} \cdot A_0$ - D, = A, A. - D3 = A, A0 Α, Dz 0 0

Multiplexer (Mux)

→ A mux has 2" data inputs, n select lines, and

one of the data inputs to The select bits are to "choose" flow through to the autput

→ Fetch

Fetch

Instruction

Operands

Operation

Decode Instruction

Evaluate Address

STANDARD SYMBOL FOR 2-bit signal Indicates a

(from memory)

D

E A

0P

EX

## Instruction Processing

#### Fetch

- 1) loads next instruction from memory store at address in PC and places into Register (IR)
- 2) PC is increment to point to next instruction

## Decode

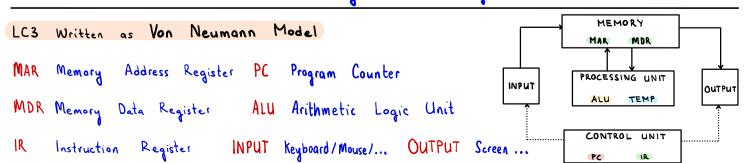

- 1) Identifies the opcode
- 2) Depending on identifies other operands from remaining opcode,

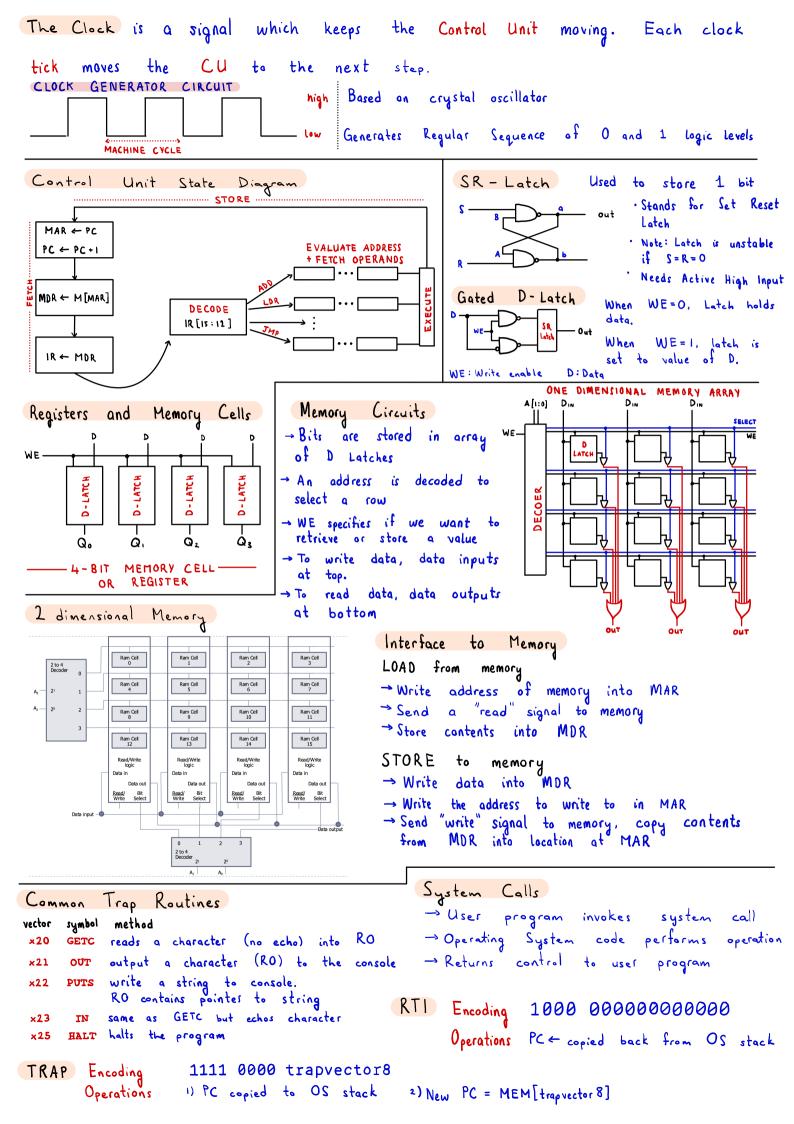

Evaluate Address - For operations that require memory access, compute address for access

Fetch Operands - Obtain source operands needed to perform operation

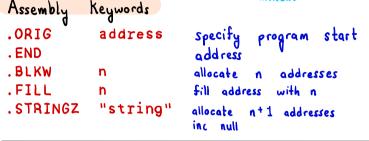

Execute - Perform the operation, using source operands

Store - Write results to destination (register or memory)

#### Subroutines JSR Encoding 0100 1 PCoffset11 → Lives in user space 1) R7 + PC 2) PC - PC + PCoffset Operations -> Performs well defined task → Invoked by another program JSRR Encoding 0100 0 00 Base 000000 → Returns control to main program Operations 1) R7 + PC 2) PC + Base R Assembly Syntax RET Encoding 1100 000 111 000000 LABEL OPCODE OPERANDS; COMMENT Operations PC + R7 -optional -De Morgan's Law mandatory signifies start of OR FORM $\overline{AB} = \overline{A} + \overline{B}$ $\overline{A + B} = \overline{A} \overline{B}$ AND FORM

### # STACKS

R1 <- Pointer to Stack Pointer R7 <- Value to Push / Value from Pop

We Push and Pop to the stack using ...
JSR Pop

JSR Pop JSR PUSH

\*\*PUSH AND POP\*\*
PUSH MEM[R1] <- R6
R6 <- R6 - 1

POP R6 <- R6 + 1 R1 <- MEM[R6]

EMPTY Specifies intial stack pointer

Memary	Mapped Controller 1/0 Register	Registers
Location	110 Register	
x FEOO	Keyboard Status Register	KBSR
xFEO2	Keyboard Status Register Keyboard Data Register	KBDR
•••		

#### Statuses

means controller can change value and toggle status

1 means controller can't change value

0 means CPU cannot read value

1 means CPU can read value and change status to 0

Visualising Stacks

THIS COURSE USES EMPTY STACK CONVENTION

IN DESC. ORDER

Stack Pointer (SP)

Change values by popping and pushing

Address specified by

note: popping from stack doesn't delete value, it just changes stack pointer

label EMPTY

Overflow and Underflow

Stack Range: x4000 -> x3FFC

Underflow SP > x4000

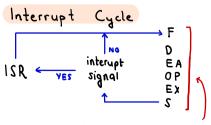

Overflow SP < x3FFC

#### I/O Controller

x 4000 s

- Provides necessary interface for 1/0 devices
- → Takes care of low level, device dependant details
- → It buffer data sent to processor so devices remain in sync

Fetch Decode Execute Cycle

ISR Interrupt Service Routine

Polling

# HOW TO USE CONTROLLER REGISTERS IN CODE

LDI R1, KBSRPtr

BRzp POLL

LDI RØ, KBDRPtr

KBSRPtr .FILL xFE00

.FILL xFE02 KBDRPtr

\*\*To Note:\*\*

- Polling is a waste of cycles

### Interupt Service Routine

When an external device needs handing ...

- ') The current program is stopped by the OS and the state is saved.
- 2) The Interrupt Service Routine is run, satisfying the 110 devices needs.
- programs state is restored and gains control over CPU.
- Interupts are assigned a priority, PO -> P6, with 6 being the highest
- Check page before for Interrupt Cycle

## Finite State Machine (control unit)

On each machine cycle FSM changes control signals for next phase of instruction processing. Like ...

- → What component drives the bus
- → Which registers are write enabled
- → Which operation should the ALU perform

### Global Bus

Set of to transfer 16 bit data to wires that allow various components components.

components may read data from the bus on One or

### LC3 Data Path should be on exam appendix

#### # C Programming Notes

#### \*\*Pointers\*\*

- \_ `\*`
  - Used to declare a variable is a pointer to another variable
    - e.g. 'int \*p = &a' | meaning p stores the memory address of a
  - Used to deobfuscate a pointer
    - e.g. `\*p = 12` | meaning the store 12 in the memory address stored in p
- '&'
  - Returns the memory address of a variable
  - e.g. `printf("%p\n", &a); ` | prints something like 0x3005

#### \*\*Formatting Strings\*\*

- `%d` or `%i`: Signed decimal integer
- `%u`: Unsigned decimal integer
- '%f': Floating point number
- `%c`: Single character
- `%s`: String (null-terminated character array)
- `%p`: Pointer address
- '%x' or '%X': Hexadecimal integer (lowercase or uppercase)

## Bitwise Operations

Operation	Operator	Examples
AND	&	a & b
OR	1	alb
NOT	~	a ~ b
XOR	^	a ^ b
LEFT SHIFT	<<	a << b
RIGHT SHIFT	>>	a >> b
	I	

Scope and Symbol Table

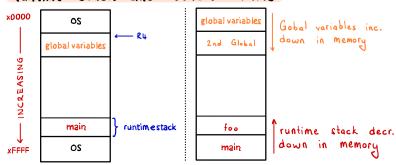

be accessed anywhere in Global can the program.

Local accessable in a particular only region.

int x, y, z; 
$$\leftarrow$$
 global int main() {
 int a, b, c;  $\leftarrow$  local

5	<b>SYMBOL</b>	. TA	BLE CON	IDENSE
1	Name	Type	Offset	Scope
} -	x y z a b c	int	0 1 2 0 -1 -2	global
	abc	int	0 -1 -2	local
1				

### Runtime Stack and Stack Frame

add recursion and stuff about Stack France.
